

APPLICATION OF RFID LABELS

SPECIFICATION

The invention pertains to a process for producing RFID labels according to the
5 introductory clauses of claims 1 and 12.

Prior Art

The invention describes various processes for producing RFID (Radio Frequency
Identification) labels, also called "smart labels". The basis of intelligent labels (RFIDs,
10 smart labels) is so-called transponder technology. Its great advantage lies in the
wireless link between the label and the reader. This can greatly accelerate the
mechanical process of data acquisition, because the reader no longer needs to be
linked optically with the label. Thus, for example, the content of a box or of a whole
pallet can be acquired without error. Security codes can also be stored in the smart
15 labels, as a result of which packages cannot be falsified (e.g., pharmaceutical industry),
and thefts can be clearly identified.

A system for wireless identification consists of two components: the RFID label
(smart label), which is attached to the merchandise, and the read/write device, which
can be used to read data from or transfer data to the label. Depending on their design,
20 the transponders store data ranging from simple identification numbers to complex sets
of data (e.g., expiration date, production site and date, sale prices, etc.). Measurement
data can also be stored. A transponder usually consists of an integrated circuit, an
antenna, and other passive components. Depending on the way in which power is

supplied, a distinction is made between active and passive transponders. If the label has its own power supply in the form of, for example, a battery, we speak of an active system. If the transponder is supplied with power by means of an external magnetic or electrical field, the system is considered passive.

5 The transponder IC, which is connected to the antenna of the mobile data storage medium, handles the transmission and reception of the data. In the case of passive RFID transponders, all of the intelligence and functionality are usually integrated into this circuit.

10 Some types also contain an on-chip resonance capacitor for an oscillating circuit, so that no other external components are required except for an antenna coil. The capacitor or capacitors required can also be produced by printing methods. Known, standard processes for the production of RFID labels include the lamination of a coated foil onto the label, the printing of the antenna by the screen printing method, and production by means of ink-jet printing.

15 When merchandise security labels, including RFID labels, are applied, the method used in the past has been to produce a single merchandise security element on a subelement, such as a small, self-adhering label, and then to apply this label to the merchandise, to its packaging, or to its transport packaging. Merchandise security elements can also be produced, as described above, by printing them directly onto the
20 packaging itself. To facilitate the application of the merchandise security elements, the merchandise security elements can be applied directly to individual packages, packaging elements, or parts of the packaging. When printing packaging elements, a sheet consists of several so-called "copies". Each copy contains the packaging or a

part of the packaging, i.e., a packaging element. This production of several copies on one sheet requires that the copies be separated from each other afterwards. This step of separating the copies can be integrated into the process of applying the merchandise security labels. After the entire sheet has been printed, it contains the preprinted sensor elements of the merchandise security element, e.g., parts of an RFID label. The next step is to attach the parts of the individual merchandise security element which respond to external sensors; these parts can be in the form of a chip. This application step is made more difficult by the fact that the copies are arranged on the sheet in such a way as to conserve space and are thus arranged in various columns and rows.

Object of the Invention

The object of the present invention is to apply the required parts to a package easily and with minimal technical effort.

This object is accomplished by the characterizing features of claims 1 and 12 in conjunction with claim 25. Elaborations of the invention can be derived from the various subclaims.

Examples

According to the invention, at least parts of the antenna and/or of the oscillating circuit which are required for the proper functioning of the device are applied to the substrate by offset printing, or at least part of the functionally required antenna and oscillating circuit are applied directly or indirectly by means of a letterpress plate. After

printing, the only further step required is to attach the chip, which usually does not have a housing, by means of a bonding or soldering process.

With respect to the design of the antenna, the following parameters are of interest: the inductance, the coil area, the ohmic (active) resistance, and the mutual capacitance between the windings. Deviations from the characteristic values can make it impossible for contact to be established between the read/write device and the transponder. The resonance frequency must also be achieved with a high level of accuracy, which means that very strict standards are imposed on the quality of the printing.

According to the invention, a metal ink or conductive paste is transferred via a waterless offset plate or a wet offset plate and via the printing blanket to the substrate within a sheet-fed or rotary web offset press. The printed lines form the antenna and possibly the entire oscillating circuit. The chip is then soldered or glued on later, if necessary. The substrate, on which the components of the oscillating circuit are printed, can be a fibrous material (paper, nonwoven, etc.), a fabric of natural or synthetic fibers, or a plastic film. Figure 1 shows a schematic top view of a label produced according to the invention.

An absorbent substrate, e.g., paper or some other fibrous material, can be pretreated to prevent the conductive ink or paste from being absorbed. The pretreatment can involve pre-inking or the application of printer's varnish by means of a flexo press or an offset press. It is also possible to laminate a film onto the back of the label or to have the back of the label pretreated by the manufacturer. If a large amount of ink is absorbed by the substrate, the inductance can change as a result of the third

plane. Application by means of a plate for waterless printing is preferred over wet offset, because the wetting agent required for wet offset printing can lead to corrosion of the ink. The precision of the printing is also higher. Waterless offset also makes it possible to obtain higher resolutions and finer lines.

5 The capacitor required to produce the oscillating circuit can be obtained by printing two lines closely together, which are connected to each other at the ends of the shorter line. Alternatively, the base line can be printed first; an insulating material is printed on top of it; and then the opposing line is printed on top of that in a third printing couple. The capacitor can also be integrated into the chip. Other circuit elements such
10 as resistors can also be printed by tapering the thickness of the lines.

In theory, the capacitor lines can be printed on both sides of the substrate so that they are opposite each other. For this purpose, it is also necessary to perforate the substrate beforehand so that a connection is established between the two opposing lines when the ink is applied.

15 Finally, the antenna and the oscillating circuit can be coated with a protective coating, which protects the printed image against mechanical, chemical, and oxidative damage. Alternatively, a protective film can be applied over them.

According to a second process, an adhesive is preprinted by passing it through a printing couple. The sheet printed with the adhesive is then brought into contact with a
20 transfer film, which has been coated with a metallic or other conductive material. At the points where the adhesive has been applied, the conductive material is separated from the carrier film and transferred to the substrate. This then forms the oscillating circuit, antenna, or certain parts of these components.

According to a third process, the lines of the antenna and/or of the oscillating circuit can be printed by means of a flexo press. The disadvantage of this, however, is that a flexo plate can lead to blurred edges if it is not positioned precisely. These blurred edges would change the capacitance and thus cause a change in the characteristics of the oscillating circuit.

To complete the RFID label, the oscillating circuit or the entire chip is added by soldering or adhesive bonding.

According to the inventive process, this final step is carried out advantageously in that the sheet is divided into individual copies or blocks of copies in such a way that the elements are oriented with respect to each other in a uniform manner. When it is time to attach the chips, the copies or blocks of copies can be fed to an applicator device in such a way that the merchandise security elements can always be processed in the same position. This greatly facilitates the application of the chips to the preprinted parts of the merchandise security elements. The completed parts can then be easily applied to the packages.

It is also possible to apply the printed basic elements directly to the package. Then the RFID label can be completed in the folding box gluing machine or in the box-filling station.

The RFID labels can thus be applied to the package, to parts of the package, or to individual elements, which are themselves applied to the package or which complete the package and which carry only one RFID label.

The schematic diagrams of Figures 2 and 3 are provided for the sake of illustration. On this basis, therefore, the following procedure is proposed:

1. Several copies of the antenna of an RFID chip are printed onto the sheet.
2. The copies are stamped out or cut out to obtain individual copies.
3. The individual copies are gathered and unidirectionally oriented.
4. The oscillating circuits or chips are then soldered or glued onto the individual
5 copies or blocks of copies.

The oscillating circuits or chips can be applied and assigned to the individual copy in a separate machine. Ideally, however, the components are applied on a production line, e.g., in a folding box gluing machine or possibly in the box-filling station.

10 This avoids the necessity of having to transfer the articles, after they have already been put in their final packaging, to an additional labeling station for application of the merchandise security elements. Another advantage of the process is that multiple copies of the antennas or additional components of the oscillating circuit can be printed at once, on the same sheet. The only remaining step is then to apply the chip to the individual copy. This makes it possible to reduce costs considerably.
